Dashboard Insights

- The dashboard shows a total of 300 patient visits generating \$275.41K in pharmacy revenue, with an average length of stay of 1.75 days. This suggests efficient patient turnover, with most services likely delivered through outpatient care.
- Disease trends indicate that malaria and flu cases fluctuate across months, showing seasonal patterns. In contrast, hypertension and diabetes remain relatively consistent, reflecting the steady burden of chronic diseases. This highlights the need for continuous medication supply planning for non-communicable diseases, alongside seasonal preparedness for infectious outbreaks.
- The relationship between patient visits and pharmacy revenue shows that higher visit numbers do not always result in higher revenue. Some months generate higher income despite moderate patient counts, suggesting more expensive prescriptions or complex treatments. This indicates that revenue is influenced more by treatment intensity and drug category than patient volume alone.
- Medication cost analysis reveals that malaria and diabetes drugs account for a significant portion of pharmacy expenditure. Strategic procurement and inventory management in these categories could improve cost control.
- At the county level, revenue contributions vary between emergency, inpatient, and outpatient services, suggesting differences in care demand and service utilization across regions. Monitoring cost per visit and disease trends will support better financial planning and operational efficiency.
